HYDROXYCARBAMIDE

INDICATION

1. Non-leukaemic myeloproliferative neoplasms (MPN):
   - Essential Thrombocythaemia (ET)
   - Primary Polycythaemia Vera (PV)
   - Rarely: Myelodysplastic Syndromes/Myeloproliferative Neoplasm (MDS/MPN overlap), Myelofibrosis

2. Chronic myeloid leukaemia (CML)
3. Chronic myelomonocytic leukaemia (CMML)
4. Palliative chemotherapy for Acute Myeloid Leukaemia (AML)

Hydroxycarbamide can also be prescribed by GPs as part of a shared care protocol by primary care for ET and PV. [Link]

Available as 500mg capsules

Note on prescribing: When used to treat haematological neoplasms (ET, PV, myelofibrosis, MDS/MPN, CML, CMML, AML) hydroxycarbamide must be prescribed on ARIA.

TREATMENT INTENT

Disease Modification

PRE-ASSESSMENT

- Ensure histology confirmed prior to administration of chemotherapy and document in notes.
- Bone marrow aspirate and trephine may be indicated
- Molecular diagnostic tests as appropriate
- Blood tests: FBC, U&E, LFTs.
- Record stage of disease
- Urine pregnancy test – for all women of childbearing age unless they are postmenopausal, have been sterilised or undergone a hysterectomy.
- Record performance status (WHO/ECOG).
- Record weight and height.
- Fertility - it is very important the patient understands the potential risk of infertility. All patients should be offered fertility advice (see fertility guidelines).
- Consent – ensure patient has received adequate verbal and written information regarding their disease, treatment and potential side effects. Document in notes all information that has been given. Obtain written consent prior to treatment.
- Hydration - in patients with bulky disease pre-hydrate with sodium chloride 0.9% 1 litre over 4-6 hours. Patients at high risk of tumour lysis refer to tumour lysis protocol.
- Treatment should be agreed in the relevant MDT.
- For patients prescribed oral chemotherapy, ensure pre-chemotherapy counselling in line with NPSA recommendation and chemotherapy measures
DRUG REGIMEN

Variable dosing depending on blood count, response and indication:

**MPN:** Recommended starting dose is typically 500mg OD which can be titrated upwards as required. Higher starting doses may be used in patients requiring more urgent count reduction.

**CML:** Hydroxycarbamide is usually given at an initial dose of 40 mg/kg daily dependent on the white cell count. The dose is reduced by 50% (20 mg/kg daily) when the white cell count has dropped below 20 x 10⁹/L. The dose is then adjusted individually to keep the white cell count at 5-10 x 10⁹/L. Hydroxycarbamide dose should be reduced if white cell counts fall below 5 x 10⁹/L and increased if white cell counts >10 x 10⁹/L are observed.

**CMML/AML:** Hydroxycarbamide may either be used in the palliative setting to control a rising white cell count (e.g. 500mg to 1000mg daily) or used at diagnosis to control a very high white cell count (for example out of hours) whilst other treatment options are discussed (usually requiring 40 mg/kg/day or 2000mg to 3000mg daily in the short term).

**CYCLE FREQUENCY**

Continuous treatment until significant disease progression or intolerable side effects.

**RESTARTING/ASSESSING RESPONSE**

Therapy should be monitored regularly by repeat blood counts and LFT’s, and the dose adjusted accordingly. Initially monitor response 1-2 weekly, if response is achieved treatment should continue indefinitely with the monitoring frequency is reduced to a maximum of 4 monthly when the blood count is fully stable.

</tbody>
</table>
DOSE MODIFICATIONS

Haematologic
Therapy should be interrupted if the WBC drops below 2.5 x 10^9/L (neutrophil <1.5 x10^9/L), or the platelet count below 100 x 10^9/L.
Adjust dose with anaemia.
Where these are the result of bone marrow suppression secondary to haematological disease, at the discretion of a consultant haematologist treatment may commence cautiously.

Non- Haematologic
Renal impairment – Although, in practice, the dose will be titrated according to response, note that impaired renal function may affect drug clearance and the following information is available:

<table>

INVESTIGATIONS
FBC, U&Es and LFTs

CONCURRENT MEDICATION
Consider Allopurinol 300mg OD for 7-28 days (starting 24-48 hours before chemotherapy) if high white cell count. Refer to Tumour Lysis Syndrome Protocol.
ET/PV: Aspirin 75mg daily (Consider prescribing concomitant PPI if appropriate). Assess bleeding risk individually.

EMETIC RISK
Minimal
ADVERSE EFFECTS / REGIMEN SPECIFIC COMPLICATIONS

- Neutropenia: this can be severe and life-threatening and patients’ neutrophil counts should be regularly monitored.
- Anaemia: requires dose-adjustment.
- Gastro-intestinal symptoms: e.g. anorexia, nausea, diarrhoea. These are usually most prominent when the patient commences the treatment and settle within a couple of weeks.
- Potentially mutagenic and genotoxic: Female patients should be advised to avoid pregnancy, and male patients should avoid causing pregnancy whilst taking hydroxycarbamide and for three months after stopping the drug. Hydroxycarbamide is present in breast milk and should be avoided when breast feeding.
- Leukaemogenesis: Non-leukaemic myeloproliferative neoplasms have an inherent risk of transformation to acute myeloid leukaemia. A number of lines of evidence support that single agent hydroxycarbamide does not increase the risk of secondary leukaemia. However, it is difficult to exclude a minor increased risk associated with hydroxycarbamide and patients should be informed of this.
- Mouth and leg ulcers with chronic use, ovarian failure, infertility
- Skin rash or skin ulcer (requires cessation of treatment)
- Increased risk of skin cancer with prolonged use, consider surveillance

TREATMENT RELATED MORTALITY

Very low
